

Up & Down — Operator & Player Runbook

50pick · 50pick.tz · how a round is generated, how it is resolved against Twelve Data, and how a player plays it. Every screenshot in this document is from the live platform.

Up & Down asks one question: **will the price be higher or lower when the clock runs out?** A *chain* is one asset at one duration. Once started it emits a round at every clock boundary, back to back, with no further operator action. Nobody types a price and nobody decides an outcome — the price comes from Twelve Data and the outcome is arithmetic.

Who can do what

Action	Role needed	Where
Approve a price source domain	Trading	Sources & categories
Add / edit / enable an asset	Owner (Admin)	Up & Down → Overview
Choose the price reading method	Owner (Admin)	Up & Down → Overview
Change the thresholds	Owner (Admin)	Up & Down → Overview
Create / edit / start / stop a chain	Trading	Up & Down → Overview
Watch rounds resolve	Trading	Up & Down → Rounds
Place a bet	Any signed-in player	/updown

The four Owner rows are Owner-only *in practice*: the roles that hold `accounting` authority cannot open the page those controls live on. Everything else is done as a Trading officer. Never use the Owner login for work a Trading officer can do — if you do, you stop finding out whether your own permissions work.

The navigation

The admin sidebar. Everything in this runbook is under **Sources & categories** and the **Up & Down** group (Overview, Rounds).

Part 1 · Generating rounds

Five steps, in this order. Steps 1–3 are once per asset. Steps 4–5 are what you repeat.

Step 1 · Approve the price source domain TRADING

Sidebar → Sources & categories

Add `twelvedata.com` and enable it. An asset can only point at a domain that is an enabled trusted source, and this is checked three times: when the asset is added, when it is enabled, and again every time a chain starts.

The allowlist is **per category**. One `twelvedata.com` row does not cover both a `crypto` asset and a `macro` one — add it under each category you will use, or the chain refuses to start.

Sources & categories.

Step 2 · Add the asset

OWNER

Sidebar → Up & Down → Overview → “+ Add asset” (top right)

You now make only two choices. Pick an **asset class**, then a **symbol**. Everything the symbol determines — category, names in all three languages, icon, decimals, minimum move and the price-source URL — is filled in and **locked**, and shown to you in a “set by the symbol” panel so you can check it.

Choice	What it means
Asset class	Crypto · Metals · Foreign exchange · Indices. This filters the symbol list.
Symbol	Twelve Data’s own symbol, e.g. BTC/USD , XAU/USD . Only symbols the platform can actually quote are offered.
Key	Yours, and never renamed afterwards. Pre-filled with a sensible suggestion.

The category is no longer yours to choose, and that is deliberate. It selects the *trading calendar*: crypto is 24/7, everything else follows the FX/metals week. On 2 August 2026 a coin was added as macro and the console then showed it “closed · opens 22:00 UTC” every weekend, for no reason. On the same afternoon an asset was added with the symbol ETH instead of ETH/USD , pointed at a page the feed cannot read — it voided **27 of 27** rounds. Neither was rejected at the time. Both are now impossible to create, in the form *and* on the server.

Before you enable it: press “Check the live feed”

The form asks the real provider, through the same two functions that settle money, and tells you one of four things:

Verdict	What to do
Would confirm	Good. It shows the price, the provider’s own quote time and the skew in seconds. Enable it.
Readable but too slow	Do not arm it. The quote is older than the staleness window, so a round cannot confirm its opening price and <i>every round will void and refund</i> while looking perfectly healthy. This is exactly what SOL/USD did — 100% void, 8 of 8 — because its quote lags about 132 s against a 90 s window.
Market is shut	Come back when it reopens. A quote read while the market is closed proves nothing. The panel tells you the reopening time.
Cannot be quoted	The provider does not carry this symbol on the current plan. Pick another.

Then switch the asset to **Enabled**. A disabled asset cannot emit rounds.

When each asset can actually run

Asset class	Trading window
Crypto	24/7, weekends included. No closed window at all.

Metals & FX	Opens Sunday 22:00 UTC (Monday 01:00 EAT), closes Friday 21:00 UTC (Saturday 00:00 EAT). Shut all Saturday. It runs <i>continuously</i> in between — there is no daily close.
-------------	---

While a market is shut the platform **refuses to open or read a round**, so you will see no results at all until it reopens. That is deliberate: the provider keeps quoting a shut market with a fresh-looking timestamp, and settling real money on a weekend gold print would pay out on a price no market ever made. The Overview's **Market** column says `closed · opens 22:00 UTC` whenever this applies.

Price source

1 tick

<https://api.twelvedata.com/quote>

The category decides the trading calendar, so it belongs to the instrument, not to you — crypto is 24/7, everything else follows the FX/metals week. A coin filed as macro is shut every weekend for no reason, which is exactly what happened to BNB.

When this asset can settle rounds. XAU/USD follows the FX/metals week: it opens Sunday 22:00 UTC (Monday 01:00 EAT) and closes Friday 21:00 UTC (Saturday 00:00 EAT), and is shut all Saturday. While it is shut the platform refuses to open or read a round, so you will see NO RESULTS AT ALL until it reopens — that is deliberate, not a fault.

Check the live feed

Asks the real provider, through the same functions that settle money.

The source domain must already be an **enabled trusted source** in the matching category — a round captures this exact link when it opens and resolves against the same link. Add it at `/admin/sources` first if it is not there yet.

Because a round resolves against the link it captured, **the source cannot be changed while any round on the asset is still unresolved**. To move it: pause the asset's chains, let the in-flight rounds settle, then edit — the next round captures the new link.

Add asset

Cancel

The guided Add-asset form, showing Metals → XAU/USD. Everything under “set by the symbol” is filled and locked, the trading window is stated before anything is created, and “Check the live feed” asks the real provider.

Assets - 4 <i>Bidhaa</i>						
KEY	NAME	SOURCE	PRECISION	CHAINS	ENABLED	
BTC	Bitcoin BTC/USD · Bitcoin	api.twelvedata.com crypto	2 dp · min 1	0/1	⚙ EDIT ASSET · ACCOUNTING ONLY	⚙ ENABLED · ACCOUNTING ONLY
GOLD	Gold XAU/USD · Dhahabu	api.twelvedata.com macro	2 dp · min 15	0/1	⚙ EDIT ASSET · ACCOUNTING ONLY	⚙ ENABLED · ACCOUNTING ONLY
SNP500	S&P 500 S&P500 · S&P 500	kitco.com macro	2 dp · min 15	0/1	⚙ EDIT ASSET · ACCOUNTING ONLY	⚙ ENABLED · ACCOUNTING ONLY
XAU	Gold XAU/USD · Dhahabu	kitco.com macro	2 dp · min 1	0/2	⚙ EDIT ASSET · ACCOUNTING ONLY	⚙ DISABLED · ACCOUNTING ONLY

An asset's price source must be an approved trusted source at /admin/sources — checked when it is added, when it is enabled, and again each time a chain starts.

The Assets card. Source domain and precision are shown per asset, and the “0/1” column is how many of its chains are running.

Step 3 · Set the reading method OWNER

Up & Down → Overview → Price reading method

Set method `feed` and provider `twelvedata`.

The other provider, `mock`, is a simulator. It **refuses by construction in production** — it will never settle a real round. If every round is voiding, check this card first.

Price reading method <i>Njia ya kusoma bei</i>	
⚙ CHANGE THE PRICE READING METHOD · ACCOUNTING ONLY	

Price reading method.

Step 4 · Create the chain TRADING

Up & Down → Overview → **Chains** card → “+ Add chain”

- **Asset** and **Duration** — **3, 5, 10, 15, 30 or 60 minutes**. *Corrected 2026-08-24: this said “5, 15 or 30”, which is half the list. The real one is `ALLOWED_DURATIONS` in `src/lib/updown-durations.ts`, and an operator following the old sentence would not have known that 3, 10 and 60 exist — 3 and 10 are running on production today.*  **The form greys the ones this asset cannot support**, from that asset’s own measured record, and the server refuses the same pairings — so a greyed option is a measurement, not a preference. If a duration you expect is unavailable, read the note beside it rather than working around it.
- **Margin %** — leave *blank*. Blank inherits the measured value for that asset class and duration, and the placeholder shows you what that is.
- **Min / max stake** — blank inherits the platform defaults.

A new chain starts **stopped**. Creating it emits nothing.

Add chain. The margin placeholder tracks the asset and duration you pick.

Step 5 · Start it TRADING

Chains card → the chain’s row → **Start**

The row then shows **RUNNING** and a **Next boundary** time. From that moment rounds appear on their own.

Chains · 0 running

Minyororo

+ Add chain

CHAIN	STATE	NEXT BOUNDARY	MARKET	MARGIN	VOID RATE	STAKE BOUNDS	CONTROLS		
BTC 5m Bitcoin	STOPPED	—	open	0.02% · sched	0% 0/7	inherit	Edit	Start	
XAU 5m Gold	STOPPED	—	closed · opens 22:00 UTC	0.02% · sched	100% 50/50	inherit	Edit	Start	
XAU 15m Gold	STOPPED	—	closed · opens 22:00 UTC	0.03% · sched	—	250 - 500,000	Edit	Start	
GOLD 15m Gold	STOPPED	—	closed · opens 22:00 UTC	0.03% · sched	100% 50/50	inherit	Edit	Start	
SNP500 15m S&P 500	PAUSED	—	closed · opens 22:00 UTC	0.03% · sched	100% 50/50	250 - 500,000	Edit	Resume	STOP

The Chains card. **Market** says whether that asset’s market is trading right now; **Margin** is the band actually in force (· sched means inherited); **Void rate** is how often its recent rounds refunded — the feedback on whether the margin suits the asset.

Pause stops new rounds and keeps the chain’s clock. **Stop** stops new rounds entirely. Both let rounds already open finish and settle normally — no player is ever left holding an unsettled stake.

Part 2 · How resolution works

This is the part to understand before testing, because a round that refunds is not a round that failed.

One price per boundary, shared

At every clock boundary the engine reads the price **once** for that asset and that instant, from `api.twelvedata.com/quote`. That single reading is written to a write-once ledger and shared by every round edge on that instant. So:

- Round N's **close** is literally round N+1's **open** — the same number, to the digit. Adjacent rounds cannot disagree.
- A reading, once confirmed, cannot be overwritten by a retry or a second server.

The freshness rule

Twelve Data reports *when it last quoted the price*. If that time is more than **90 seconds** from the round boundary, the reading is **refused** — we never settle on a price we cannot date to the moment the round ended. A refused boundary is retried on a backoff ladder; if it never confirms, the round **voids and every stake is refunded in full**.

The winning band (the margin)

At open, the round freezes two targets: `open + margin` and `open - margin`, where margin is a percentage of the opening price. At close:

Close price	Outcome
at or above the UP target	UP — Up backers win
at or below the DOWN target	DOWN — Down backers win
anywhere between	VOID — every stake refunded in full, no fee

The band is frozen at open, so changing the margin later only affects future rounds. A bet already taken can never be re-priced.

The margin is the one setting that decides whether the game feels alive. Too wide and almost every round refunds; too narrow and a one-cent flicker decides real money. The defaults were measured against roughly a thousand real windows per duration and land at about one round in three refunding: **0.02% at 5 minutes, 0.03% at 15, 0.05% at 30**. Leave the field blank unless you are deliberately tuning one asset.

Market hours

Crypto trades 24/7. Metals, FX and indices do not: their week runs **Sunday 22:00 UTC to Friday 21:00 UTC**. Outside that window no round opens and none settles, and the Chains card says `closed · opens 22:00 UTC`. This is deliberate — a data provider will still answer at the weekend, and settling real money on a market that is shut is not something the platform will do.

What a round pays

Winners split the pool after the platform’s commission — **13% of the pool, capped at a third of the smaller side**. On a balanced TZS 10,000 pool that is TZS 1,300. Frozen onto each round at creation. The × 1.4 est. on the buttons is an *estimate*, never fixed odds, and the card says so.

Every round, its open and close prices, its band, its outcome and when it settled.

Part 3 · Playing

Top navigation → Up & Down (/updown)

Pick the asset, then the duration. The strip underneath shows the last few outcomes, oldest to newest.

A live round. Read it top to bottom: the countdown; the pool and how many players; the Up/Down split; **Target to win** — the two frozen prices and the $\pm$ band; your own position if you have one; the stake chips; the two bet buttons. The footer names the source, the time it quoted, and the opening price.

1. Pick a stake — a chip, or **Custom**.
2. Tap **Up** or **Down**.

There is **no confirmation step** on this game. The first tap places the bet and takes the money — that is the design for a five-minute round. Check the stake chip before tapping.

Betting closes *at* the boundary, because the bet is on the price at that instant.

The same round as the picture above, once settled. Both prices — open \$63,114.00 → close \$63,058.00 — the band it had to clear, how far it actually moved, and the source line naming `api.twelvedata.com` and the time it quoted. This is what makes the result checkable by the person whose money it was.

The settlement proof

Every settled round carries an **auditable record** below the card: each price with its own source, the time the provider quoted it and the time we observed it, the outcome, and an excerpt of the raw provider response. A tester should not take our word for a result — this is the panel that lets them check it.

The outcome tile from that record. Note the **Rule** line: a round is decided against the *targets*, not against the opening price. A close between them is a void, however far the price moved.

What a player sees when the chain is **not started**. If a tester reports “the game is empty”, this is it — check the chain’s state, not the feed.

Top navigation → **History** (/updown/history)

Every round the player has taken, with the prices and the net return.

Up & Down does **not** send a notification for each win or loss — a player running twelve rounds an hour would get twelve messages. The result is on the round card and in History. Money movements are always recorded in the wallet and on the statement.

Part 4 · Testing it, and reading a failure correctly

A test that proves the game works

1. As Trading, start a **5-minute crypto** chain (crypto so market hours cannot confuse the result).
2. As **two different players**, back opposite sides of the same round.
3. Wait for the boundary. Do nothing else — settlement is automatic.
4. Check, in this order:
 - the round has an **open price and a close price, and they differ**;
 - the outcome matches the direction those two prices moved;
 - the winner's wallet went up and the loser's stayed down;
 - stake in – paid out = the commission.

Read the **prices**, never just the outcome flag. Two identical prices with a VOID means the feed gave the same number twice; two different prices with a VOID means the move was inside the band. Those look identical in an outcome column and mean completely different things.

Every round is voiding — what to check, in order

1. **Is the chain running?** Chains card → State.
2. **Is the market open?** Chains card → Market. A shut metals market opens nothing.
3. **Is the provider** `twelvedata`, **not** `mock` ? Price reading method card.
4. **Is the margin far too wide?** Chains card → Void rate. A high void rate with healthy prices means the band, not the feed.
5. **Is the domain approved for that asset's category?** Sources & categories.
6. **Only then suspect the feed.** Round detail shows the refusal reason in words.

The refusal reasons say different things and send you to different places: *market closed* is the calendar; *stale* means a price arrived but too far from the boundary; *no-move* means the price moved less than the band; *unparseable* or *wrong source* means the asset is pointing somewhere it should not be.

What a void is not

A void is not a loss and not an error. Every stake comes back in full and no commission is taken. It is the platform declining to decide, which is the correct behaviour whenever the price cannot be established or the move was too small to call.

Prepared for operator and player testing on `50pick.tz`. Screenshots captured from the live platform, 2026-08-02. Round `udr_0c015a854aa105600373` is the worked example: opened 63,114.00, closed 63,058.00, band ±\$12.62, resolved DOWN, settled 441 ms after its own boundary, paid TZS 8,700 to the Down backer against the Up backer's loss, commission TZS 1,300.
